Diacylglycerol kinase (DGK) catalyzes the phosphorylation of diacylglycerol and is a key enzyme in the regulation of signaling through the phosphatidylinositol 3-kinase (PI3-kinase) and diacylglycerol kinase C (DGKC) signaling pathways. The four isoforms of DGK, alpha, beta, gamma, and delta, can be grouped into DGK alpha and DGK beta based on their molecular weight, tissue distribution, and functional properties. We have identified and characterized the mouse DGK alpha and beta genes, and used gene targeting to determine their function in mammalian development. The mouse DGK alpha gene is located on chromosome 11 and codes for a 585-amino acid protein of 59.8 kDa. DGK alpha transcripts are expressed at relatively high levels in most mouse tissues. The murine DGK alpha gene is highly homologous to the human and rat genes at the amino acid sequence level, including high levels of homology at the genomic level. DGK alpha mRNA is detected in early embryos at the 2-cell stage. DGK beta mRNA is absent from mouse oocytes
